This study aims to estimate whether estrogen only (ESO) or oral estrogen and progesterone (E+P) early in life reduces the risk of hip osteoarthritis (OA). Relevant studies were identified through systematic searches of PubMed and Web of Science until November 2018. The primary outcomes included the incidences of hip OA and osteoporosis. A network meta-analysis was performed to combine direct and indirect evidence for ESO versus E+P. In the main model, the effect of ESO was compared to that of E+P. In a sensitivity analysis, we performed a conventional meta-analysis using a fixed-effects model for the same comparisons. The inverse variance method and random-effects model were used to perform network meta-analyses. The primary outcomes were not associated with ESO or E+P. ESO might contribute to a higher incidence of hip OA (OR = 1.93; 95% CI: 0.79, 4.66), but the evidence was limited due to a high level of heterogeneity. E+P might reduce hip OA by up to 58% (OR = 0.42; 95% CI: f30f4ceada
